When I search online, I always find that the lightest superconductor is the superconducting state of the hydrides. I understand why the hydrides are not the lightest superconductor. The reason is that they become superconducting when the network is undoped. The interstitial H atoms break the electronic structure of the metal sheet, but we want to form a superconductor with the least number of broken bonds. This is why HS\_2S is not a superconductor. However, if we filled the interstitials, then we would not have a superconductor because we cannot have a fully occupied valence band. This leads to my question: why is the hydride not the lightest superconductor? All the metals with superconducting properties are metals with free electrons. Hydride is also made of a metal. A: The reason is that we want to form a superconductor with the least number of broken bonds. So why do you care about the number of broken bonds? This is why HS\_2S is not a superconductor. Why do you care that HS\_2S is not a superconductor? It does have exactly one pair of electrons in a singlet state. This single electron pair can engage in tunneling via any of the many ways in which an electron can interact with an impurity. So the rule for superconductivity is: any number of electron pairs can pair-annihilate. The hydrides don't meet this criterion, so they are not superconductors. Further to your comment about the doping of the hydride: it
